

Dear Editors,

I am pleased to submit “**Why Fixed Protections Fail Under Rising Coordination: A Structural Failure-Mode Transition in Coupled Systems**” for consideration as a research article in *Nature Communications*.

What we found. Modern governance relies on passive stabilizers — fixed-rule mechanisms like portfolio diversification, constitutional checks, and AI safety filters that buffer shocks at fixed strength. We show that these mechanisms are structurally insufficient at high coupling. In mean-field coordination models, a fixed protective field loses effectiveness as the square of the coupling, with an irreducible residual at high coupling that an active (scaling) stabilizer eliminates entirely. The framework yields a structurally unique prediction — a **failure-mode transition**: as coupling rises, the *type* of failure shifts from fragmentation to rigidity. We confirm this in 22 years of S&P 500 sector data — the model’s predicted type-composition curve matches the empirical curve with near-perfect rank correlation — and replicate the pattern in cryptocurrency markets, where supercritical coupling is the typical regime.

Why it matters. The finding reframes governance design: the question is not whether protections are strong enough but whether they are the right *kind*. Current AI governance — capability evaluations, content filters, alignment fine-tuning — falls almost entirely on the passive side. Direct measurement of frontier-model output coupling places AI above the model’s critical threshold, and universal jailbreaks — adversarial strings that bypass multiple models’ independent safety training simultaneously — instantiate exactly the passive-stabilizer failure the framework predicts. The paper does not merely describe the failure mode; it derives the structural class to which any effective intervention must belong: mechanisms whose response scales with the measured threat.

Why *Nature Communications*. This work synthesizes statistical physics (Curie–Weiss mean-field theory), financial economics (asymmetric dependence, diversification failure), AI safety (adversarial transfer), and comparative politics (institutional erosion under polarization) into a single framework. *Nature Communications*’ interdisciplinary mission and recent record in complex-systems research applied to social dynamics — including Iacopini et al. (2024), Horne et al. (2022), and Ferraz de Arruda et al. (2023) — make it the natural venue for a contribution that sits across disciplines no single-field journal can adequately assess.

Practical information.

- ~5,000 words main text; ~2,000 words Methods; 8 main-text figures; Supplementary Information (§S1–§S11, Figures S1–S6).
- All code, data, sweep outputs, and figure-generation scripts are released under the MIT License at a public GitHub repository (github.com/dancing4am/failure-mode-transition) and permanently archived on Zenodo (DOI: 10.5281/zenodo.20061432).
- Empirical data are openly available (Yahoo Finance for equity returns, FRED for macro series, V-Dem and Our World in Data for political indicators, AlpacaEval v2 for model outputs).
- The manuscript is not under consideration at any other journal. A companion governance commentary is in preparation for separate submission to a policy venue.

Suggested reviewers. Jón Daníelsson (LSE) — endogenous risk; Stefano Battiston (UZH) — systemic risk and complex networks; Dirk Helbing (ETH Zurich) — social physics; Vitor Vasconcelos (UvA) — evolutionary game theory on networks; Matthew O. Jackson (Stanford) — network economics.

Excluded reviewers. None.

I look forward to your editorial assessment.

Sincerely,

Chowon Jung
